## 4 Conclusion

# Introduction

Overall objective : semantic categorisation.

- Use spatial information.
- Global representation.

# State of art

## Bags of feature

- Images described as an orderless collection of features.
- Good performances.
- Do not use the information about the spatial layout of the features.

## Multiresolution histograms

Subsampling an image and compute a global histogram at each level.

## Generalized histograms to locally orderless images

For each Gaussian aperture at a given location and scale, the locally orderless image returns the histogram of image features aggregated over that aperture.

## 4 Conclusion

# Pyramid Match Kernel

## Goal

Find the approximate correspondance between 2 set of vectors,  $X$  and  $Y$ , in a  $d$ -dimentional feature space.

## Idea

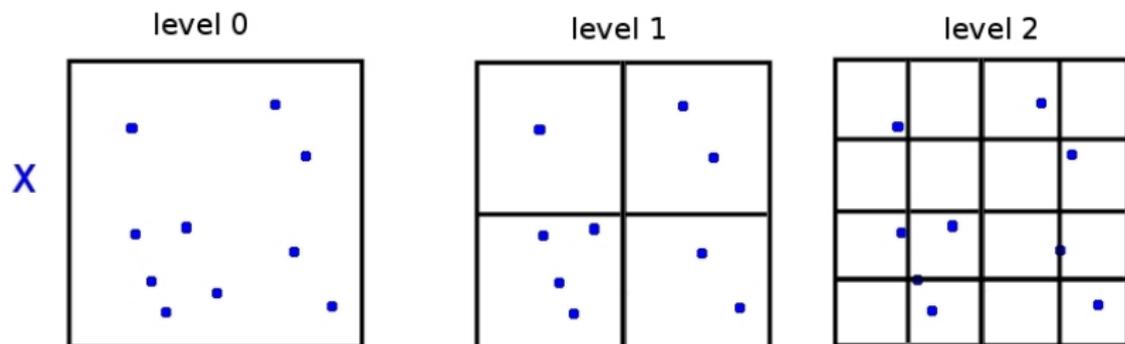

- correpondances are computed at different levels of resolution.
- at each level, a finer grid is set on the space.
- 2 vectors are said to match if they are on the same cell.
- take the weighted sum of all the matches.

# Subdivisions of the feature space

We compute matches at different level of resolution  $0, \dots, L$ .

At the level of resolution  $l$

- the grid is divided in  $2^l$  along each dimension.
- the grid has  $D = 2^{dl}$  cells where  $d$  is the number of dimensions.

# Histograms intersection

## Histograms of X and Y

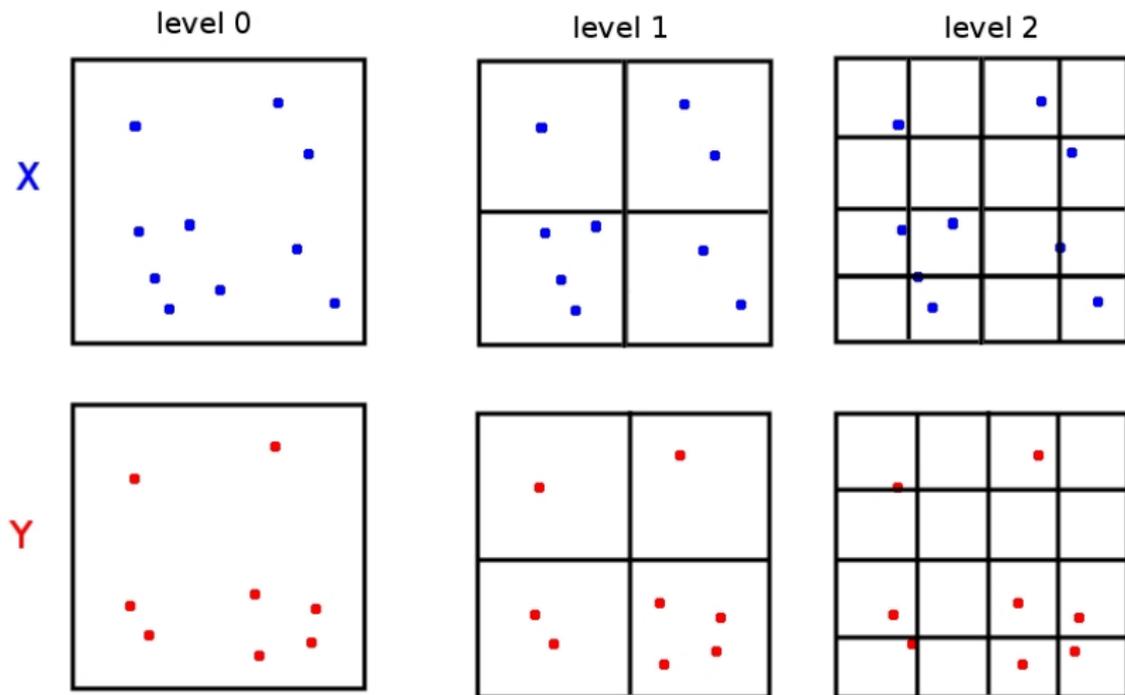

$H_X^l$  and  $H_Y^l$  are the histograms of X and Y at level  $l$   
where  $H_X^l(i)$  is the number of vectors of X in the  $i$ th cell of the grid.

## Histogram Intersection function

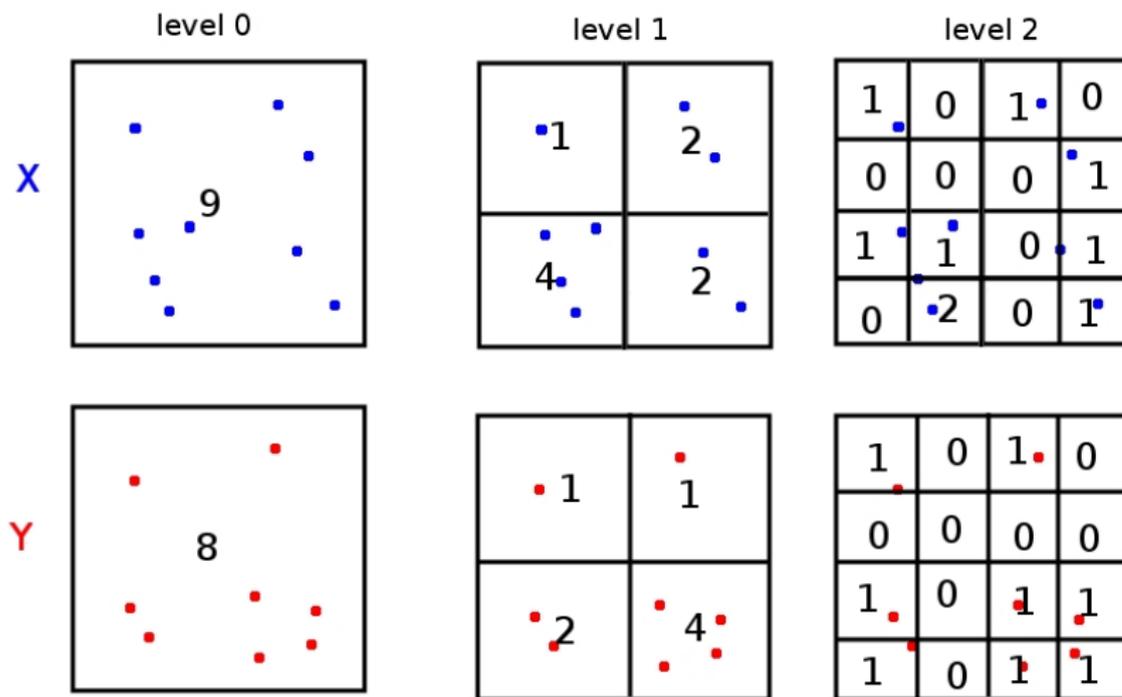

Give the number of matches at level  $l$  :

$$\mathcal{I}(H_X^l, H_Y^l) = \sum_{i=1}^D \min(H_X^l(i), H_Y^l(i))$$

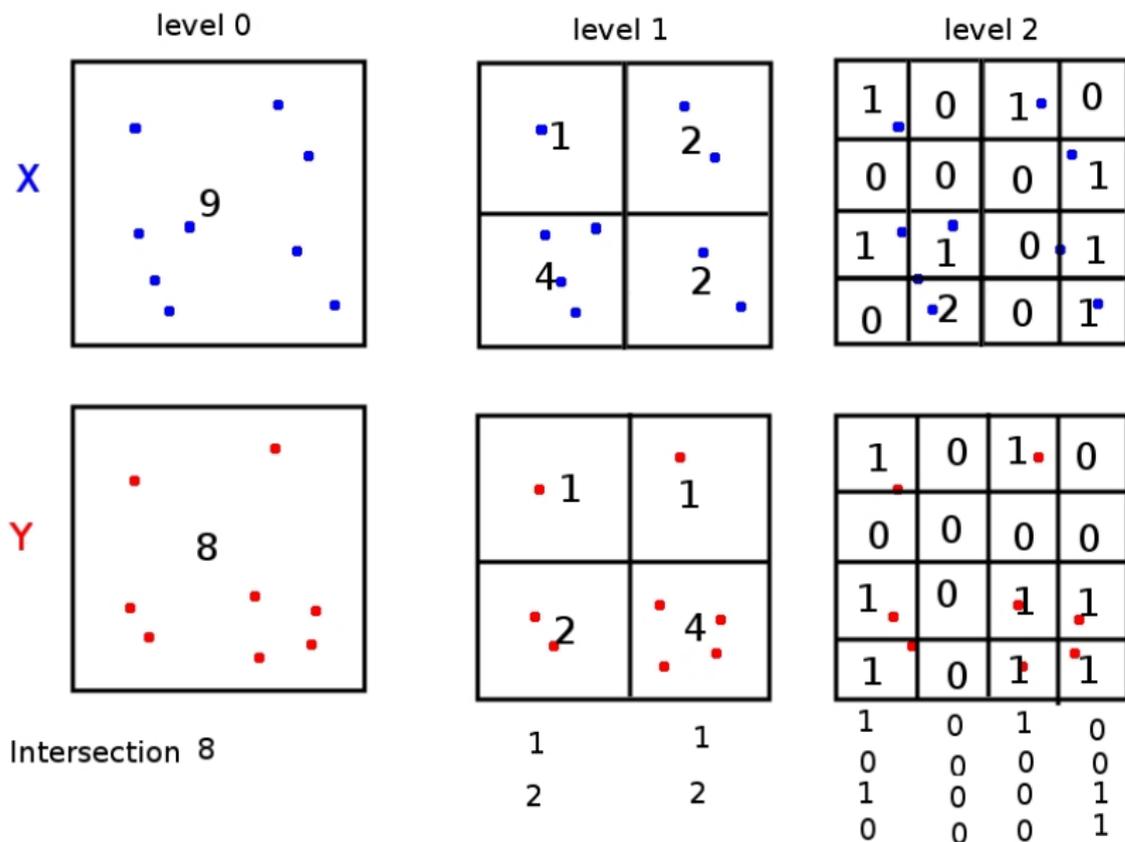

# Histograms intersection

# Histograms intersection

# Histograms intersection

# Computation of the kernel

All matches found at level  $l + 1$  are found also at level  $l$ .

→ Number of new matches at level  $l$  is given by  $\mathcal{I}^l - \mathcal{I}^{l+1}$ . We sum all the matches weighted by  $\frac{1}{2^{L-l}}$ . The more the grid is coarse, the less the matches are weighted.

## pyramid match kernel

Mercer kernel :

$$\kappa^l(X, Y) = \mathcal{I}^L + \sum_{l=0}^{L-1} \frac{1}{2^{L-l}} (\mathcal{I}^l - \mathcal{I}^{l-1})$$

- Graz Dataset

## 4 Conclusion

## “Orthogonal” approach

Matching of two collection of features in a high-dimensional appearance space

- quantize all feature vectors into  $M$  discrete types, giving  $M$  channels.
- perform pyramid matching in the 2-dimensional image space for each channel  $m = 1..M$ .

### Assumption

Only features of the same type  $m$  can be matched to one another.

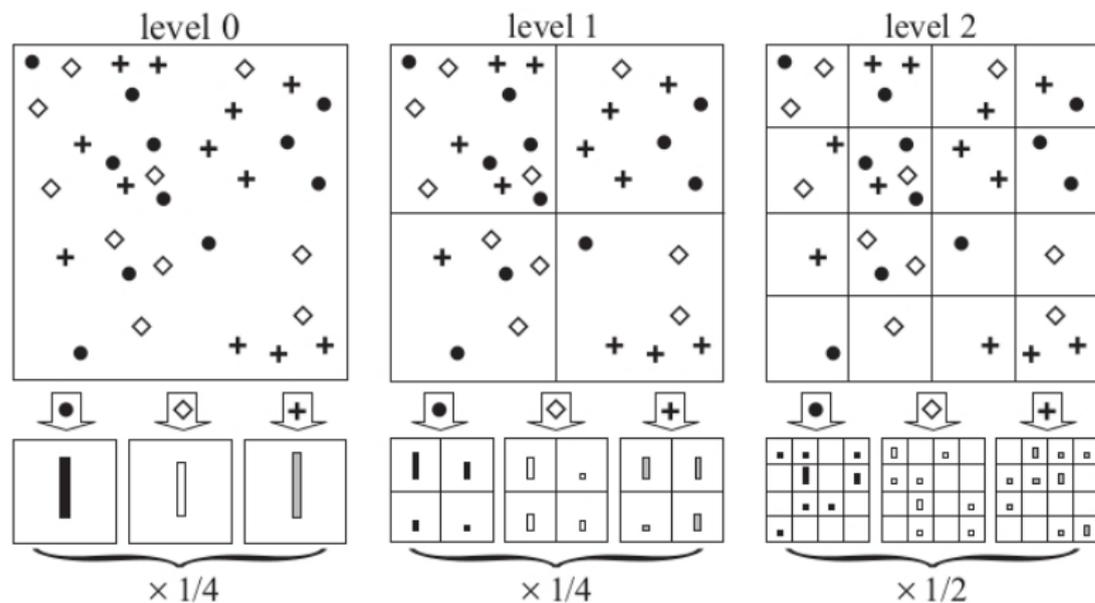

Final kernel is the sum of separate channel kernels

$$K^L(X, Y) = \sum_{m=1}^M \kappa^L(X_m, Y_m)$$

where  $X_m$  and  $Y_m$  are the coordinates of features of type  $m$  found in the respective image.

$K_L$  can be computed as the intersection of the histograms obtain by concatenating the histograms of each channel.

# Example

## 1 State of art

## 2 Method

- Pyramids
- Spatial Matching Scheme
- **Features extraction**
- Summary

## 3 Results

- Scene Category Recognition
- Caltech-101
- Graz Dataset

## 4 Conclusion

# Two kinds of features for the experiments

## Weak features

Edge points at two scales and eight orientations.

→  $M = 16$  channels.

## Strong features

SIFT descriptors of  $16 \times 16$  pixels.

$k$ -mean clustering to get a visual vocabulary.

In the experiments vocabulary size is  $M = 200$  or  $M = 400$ .

## 4 Conclusion

# Summary of the method

- Clustering features from a training set.
- Computation of the “description” of a query image.
- Comparison with the description of each image in test set.

- **Graz Dataset**

## 4 Conclusion

# Graz Dataset

Class	$L = 0$	$L = 2$	Opelt [14]	Zhang [25]
Bikes	$82.4 \pm 2.0$	$86.3 \pm 2.5$	86.5	92.0
People	$79.5 \pm 2.3$	$82.3 \pm 3.1$	80.8	88.0

- 1 State of art
- 2 Method
- 3 Results
- 4 Conclusion**

# Conclusion

- “holistic” approach for categorisation.
- Simple method.
- Gives better results than bag-of-features.
