#### Segmentation Driven Object Detection with Fisher Vectors

Camille BRASSEUR

#### Introduction

- State of the art
- Method
- Evaluation
- Conclusions

## Sliding Window approaches

Detection windows of various scale and aspect ratios evaluated at many positions accress the image.

- $\bullet$  (Viola and Jones) : cascade  $\Rightarrow$  less windows to examine
- two or three-stage approaches : windows are discarded at each stage + richer features
- branch and bound scheme (non-exhaustive search)
- prune the set of candidate windows without using class specific information by relying on low-level contours and image segmentation

The last idea is used there.

# Contributions

## **Fisher Vector**

They were already used in previous approaches. But here, normalization of the FVs.

### Segmentation

- image segmentation created for the detection
- computation of a mask with a weight for each pixel linked with its contribution to the descriptors.

Introduction

State of the art

Method

Evaluation

Conclusions

## State of the art

- extraction of explicit segmentation for each object detection hypothesis
- scoring superpixels individually and then assemble them into object detections
- use of the output from a semantic segmentation to improve object detection.

Introductior

State of the art

Method

Evaluation

Conclusions

Steps

- partition of the image into superpixels
- hierarchically group the superpixel into a segmentation tree (merging neighboring and visually similar segments)

This is repeated eight times with

- 4 different color spaces and
- 2 different scale parameters

to compure the superpixels.

 $\Rightarrow$  rich set of segments of varying sizes and shapes

(around 1500 object windows per image)

It is far less windows than in a sliding window approach.

Introduction

State of th art

Method

Evaluation

Conclusions

## Normalized gradients

$$\frac{\partial \ln p(x)}{\partial \mu_{kd}} = \frac{p(k|x)}{\sqrt{\pi_k}} \left(\frac{x_d - \mu_{kd}}{\sigma_{kd}}\right) \tag{1}$$

$$\frac{\partial \ln p(x)}{\partial \sigma_{kd}} = \frac{p(k|x)}{\sqrt{\pi_k}} \left( \frac{(x_d - \mu_{kd})^2}{\sigma_{kd}^2} - 1 \right)$$
(2)

x local descriptor

 $\mu_{kd}$  and  $\sigma_{kd}$  mean and standard derivation of the k-th Gaussian in dimension d

 $\pi_k$  mixing weight of the k-th Gaussian

p(k|x) soft assignment of x to the k-th Gaussian

Segmentation Driven Object Detection with Fisher Vectors

> Camille BRASSEUR

Introduction

State of the art

Method

Evaluation

Conclusions

### Representation :

- sum the normalized gradients
- Weight the contribution of local descriptors by the averaged segmentation masks

### Final window descriptor :

- concatenation of FV obtained over color and SIFT
- FV over the full image to capture global scene context
