Generic sparse optimization problem

Optimization problem with cardinality penalty:

$$\min_w L(X^T w) + \lambda \|w\|_0.$$

- ▶ Data: $X \in \mathbf{R}^{n \times m}$.
 - ▶ Loss function L is convex.
 - ▶ Cardinality function $\|w\|_0 := |\{j : w_j \neq 0\}|$ is non-convex.
 - ▶ λ is a penalty parameter allowing to control sparsity.
-
- ▶ Arises in many applications, including (but not limited to) machine learning.
 - ▶ Computationally intractable.

Robust Optimization

- Robust low-rank LP
- Low-rank LASSO

Classical approach

A now classical approach is to replace the cardinality function with an l_1 -norm:

$$\min_w L(X^T w) + \lambda \|w\|_1.$$

Pros:

- ▶ Problem becomes convex, tractable.
- ▶ Many "recovery" results available.

Cons:

- ▶ Is neither a lower nor an upper bound in general.
- ▶ Fails completely in some cases (see next).

- Low-rank LASSO

The l_1 -norm may fail

The l_1 -norm approach may fail to allow to *control* the level of sparsity of the solution.

- ▶ When the variable is restricted to be a *discrete distribution*, the l_1 -norm is constant, and the level of sparsity cannot be controlled.
- ▶ If the data matrix X is *low-rank*, the cardinality of the solution may be also hard to control.

Example:

LASSO with rank-one data matrix

$$\min_w \|(qp^T)w - y\|_2 + \lambda \|w\|_1,$$

with $p \in \mathbf{R}^n$, $q, y \in \mathbf{R}^m$. Solution for $\lambda > 0$ has cardinality one or zero.

Sparse Probability Optimization

Generic sparse probability optimization problem:

$$p^* := \min_w L(X^T w) + \lambda \|w\|_0 : w \geq 0, \mathbf{1}^T w = 1.$$

- ▶ l_1 -norm approach fails to control sparsity.
- ▶ Applications: index fund construction, exemplar-based clustering.

Sparse probabilities

Norm-ratios approach

Recovery

Applications

Extensions

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Proposed Approach

Basic bound:

$$\|w\|_1 \leq \|w\|_0 \|w\|_\infty.$$

Yields a *lower bound* on the original problem:

$$\begin{aligned} p^* &= \min_w L(X^T w) + \lambda \|w\|_0 : w \geq 0, \mathbf{1}^T w = 1 \\ &\geq \hat{p} := \min_w L(X^T w) + \lambda \frac{\|w\|_1}{\|w\|_\infty} : w \geq 0, \mathbf{1}^T w = 1. \end{aligned}$$

Fact: The lower bound can be computed as a sequence of n uncoupled *convex* problems:

$$\hat{p} = \min_{1 \leq i \leq n} \min_w L(X^T w) + \lambda \frac{1}{w_i} : w \geq 0, \mathbf{1}^T w = 1.$$

Checking approximation quality

Let \hat{w} be a solution to

$$\hat{p} = \min_{1 \leq i \leq n} \min_{w: w \geq 0, \mathbf{1}^T w = 1} L(X^T w) + \frac{\lambda}{w_i}.$$

We then have the bounds:

$$L(X^T \hat{w}) + \lambda \|\hat{w}\|_0 \geq p^* \geq \hat{p}. \quad (1)$$

- ▶ The quality of approximation can be easily checked when the n convex programs are solved.
- ▶ In contrast, ℓ_1 regularization does not have such a property since it is not a lower bound or upper bound. Known guarantees are not checkable in polynomial time, *e.g.*, *Restricted Isometry Property* (Candés & Tao, 2005).

Theoretical results for a special case

Problem: recover the sparsest probability measure given moment constraints:

$$p^* = \min_w \|w\|_0 : X^T w = y, \quad w \geq 0, \quad \mathbf{1}^T w = 1,$$

where $y \in \mathbf{R}^m$ is given. This is a special case of our generic problem, with L the indicator of the affine set $\{w : X^T w = y\}$.

Our bound is $p^* \geq \hat{p} = 1/(\max_{1 \leq i \leq n} q_i)$, where each q_i is the optimal value of a linear program:

$$q_i := \max_w w_i : X^T w = y, \quad w \geq 0, \quad \mathbf{1}^T w = 1.$$

Robust Optimization

Robust low-rank LP
Low-rank LASSO

Recovery result: geometric property

Assume that the unique solution of p^* is given by w^* ; let S be the support of w^* , and let S_c be its complement. If $\mathbf{Conv}(X_{S_c})$ does not intersect an extreme point of $\mathbf{Conv}(X_S)$ then $\hat{w} = w^*$, *i.e.* the approximation is exact.

Consequence: For $X \sim$ iid Gaussian, this happens with very high probability if n is $\mathcal{O}(\|w^*\|_0)$.

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Application: Index Tracking

Given a time-series matrix of prices of n assets over m days
 $X = [x_1, \dots, x_m]$, reconstruct a given financial index time-series
 y_1, \dots, y_m as a convex combination of n assets using as few assets as
 possible:

$$p^* = \min_{w \geq 0, \mathbf{1}^T w = 1} \left\| X^T w - y \right\|_2^2 + \lambda \|w\|_0.$$

The l_1 -norm approach fails in this case.

Proposed approach:

$$p^* \geq \hat{p} = \min_{1 \leq j \leq n} \min_{w \geq 0, \mathbf{1}^T w = 1} \left\| X^T w - y \right\|_2^2 + \frac{\lambda}{w_j}.$$

Solved by n second-order cone programs.

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Application: clustering

Maximum-likelihood mixture fitting

Given data $\{z_1, \dots, z_n\}$ of d -dimensional vectors, consider fitting a parametric iid distribution p_θ via maximizing the log-likelihood over the parameter θ

$$\max_{\theta} \frac{1}{n} \sum_{i=1}^n \log p_\theta(z_i).$$

Consider a mixture of Gaussians distribution with k centers:

$$p_{w, \mu_1, \dots, \mu_k}(z) \sim \sum_{j=1}^k w_j e^{-\beta \|z - \mu_j\|_2^2}.$$

with **unknown** mixture weights vectors $w \in \mathbf{R}^k$, $w \geq 0$, $\mathbf{1}^T w = 1$, **unknown** mean vectors $\mu_j \in \mathbf{R}^d$ and **fixed** known covariances $\frac{1}{\beta} I_{d \times d}$.

The problem of fitting the mixture distribution becomes:

$$\max_{w, \mu_1, \dots, \mu_k} \frac{1}{n} \sum_{i=1}^n \log \sum_{j=1}^k w_j e^{-\beta \|z_i - \mu_j\|_2^2}.$$

This is a non-convex problem and is very hard to solve.

Robust low-rank LP

Low-rank LASSO

Convex clustering

The exemplar-based model

Exemplar-based model (Lashkari & Golland, NIPS, 2008): assumes that each cluster mean μ_j is equal to some data point (“example”) z_i .

The problem is now convex:

$$\max_{w \geq 0, \mathbf{1}^T w = 1} \frac{1}{n} \sum_{i=1}^n \log \sum_{j=1}^n w_j e^{-\beta \|z_i - z_j\|_2^2}.$$

Since $k = n$ there are a **maximum number of clusters in the mixture!** .

Our bound

Idea: penalize the cardinality of the mixture to control the number of clusters

$$p^* := \max_{w \geq 0, \mathbf{1}^T w = 1} \sum_{i=1}^n \log \left[\sum_{j=1}^n w_j K_{ij} \right] - \lambda \|w\|_0$$

where K ($K_{ij} = e^{-\beta \|z_i - z_j\|_2^2}$) is a kernel matrix that can be pre-computed.

Our bound: $p^* \leq \hat{p}$, with

$$\hat{p} := \max_{1 \leq k \leq n} \max_{w \geq 0, \mathbf{1}^T w = 1} \sum_{i=1}^n \log \left[\sum_{j=1}^n w_j K_{ij} \right] - \frac{\lambda}{w_k}.$$

For every k , an SOCP!

This strategy can be applied to almost every cardinality problem. Not only in the probability simplex!

- ▶ Basis Pursuit Denoising:

$$p^* = \min_w \|w\|_0 : \|X^T w - y\|_2 \leq \epsilon. \quad (2)$$

- ▶ Sparse Support Vector Machines:

$$p^* = \min_{w,b} \|w\|_0 : y_i(w^T x_i + b) \geq 1, \quad i = 1, \dots, m.$$

The corresponding lower-bound approximations \hat{p} can be solved using n convex programs.

- ▶ Provides a lower and upper-bound on p^* (ℓ_1 formulations are neither a lower nor an upper bound).
- ▶ In sparse recovery (2), it provably outperforms its ℓ_1 variant LASSO with Gaussian iid design.
- ▶ Preprints and code: www.eecs.berkeley.edu/~mert.

Robust Optimization

- Robust low-rank LP
- Low-rank LASSO

Approach: robust low-rank LP

For the LP

$$\min_x c^T x : Ax \leq b,$$

with many instances of b, c :

- ▶ Invest in finding a low-rank approximation A_{lr} to the data matrix A , and estimate $\epsilon := \|A - A_{lr}\|$.
- ▶ Solve the *robust counterpart*

$$\min_x c^T x : (A_{lr} + \Delta)x \leq b \quad \forall \Delta, \quad \|\Delta\| \leq \epsilon.$$

- ▶ Robust counterpart can be written as SOCP

$$\min_{x,t} c^T x : A_{lr}x + t\mathbf{1} \leq b, \quad t \geq \|x\|_2.$$

- ▶ We can exploit the low-rank structure of A_{lr} and solve the above problem in time linear in $m + n$, for fixed rank.

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Low-rank LASSO

In many learning problems, we need to solve many instances of the LASSO problem

$$\min_w \|X^T w - y\|_2 + \lambda \|w\|_1.$$

where

- ▶ For all the instances, the matrix X is a rank-one modification of the same matrix \tilde{X} .
- ▶ Matrix \tilde{X} is close to low-rank (hence, X is).

In the topic imaging problem:

- ▶ \tilde{X} is a term-by-document matrix that represents the whole corpus.
- ▶ y is one row of \tilde{X} that encodes presence or absence of the topic in documents.
- ▶ X contains all remaining rows.

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Robust low-rank LASSO

The robust low-rank LASSO

$$\min_w \max_{\|\Delta\| \leq \epsilon} \|(X_{lr} + \Delta)^T \mathbf{w} - \mathbf{y}\|_2 + \lambda \|\mathbf{w}\|_1$$

is expressed as a variant of “elastic net”:

$$\min_w \|X_{lr}^T \mathbf{w} - \mathbf{y}\|_2 + \lambda \|\mathbf{w}\|_1 + \epsilon \|\mathbf{w}\|_2.$$

- ▶ Solution can be found in time linear in $m + n$, for fixed rank.
- ▶ Solution has much better properties than low-rank LASSO, e.g. we can control the amount of sparsity.

Robust Optimization

Robust low-rank LP

Low-rank LASSO

Rank-1 LASSO (left) and Robust Rank-1 LASSO (right) with random data. The plot shows the elements of the solution as a function of the l_1 -norm penalty parameter.

- ▶ Without robustness ($\epsilon = 0$), the cardinality is 1 for $0 < \lambda < \lambda_{\max}$, where λ_{\max} is a function of data. For $\lambda \geq \lambda_{\max}$, $w = 0$ at optimum. Hence the l_1 -norm fails to control the solution.
- ▶ With robustness ($\epsilon = 0.01$), increasing λ allows to gracefully control the number of non-zeros in the solution.
